

# MILLER INDICES

## ❖ Introduction:

- ❖ Miller indices were introduced in 1839 by the British mineralogist William Hallowes Miller.
- ❖ The method of representing orientation of crystal planes was historically known as the Mellerian system and the indices as Mellarian.
- ❖ The planes passing through the lattice points are called Lattice planes.

## ❖ Definition:

- ❖ Miller evolved a method to designate a set of parallel planes in a crystal by 3 numbers ( $h$   $k$   $l$ ) known as Miller indices. (or)
- ❖ The reciprocal of the intercepts made by the plane on the crystallographic axes (when reduced to smallest numbers) are known as Miller indices.
- ❖ Miller indices are represented by a set of numbers ( $h$   $k$   $l$ ), used to identify the plane or surface in a crystal.
- ❖ Steps in the determination of Miller indices (or) procedure for finding Miller indices:

- ❖ **Step 1:** Choose the System of three coordinate axes (Crystallographic axes) x, y, & z.
- ❖ **Step 2:** Determine the intercepts P, Q, & R of the required plane ABC on these axes  
i.e.,  $OA = p$ ,  $OB = q$  and  $OC = r$ .
- ❖ **Step 3:** Take ratio of reciprocals of the intercepts, i.e.,  $1/p : 1/q : 1/r$
- ❖ **Step 4:** Convert these reciprocals into integers by multiplying each one of them with their LCM  $pqr$   
i.e.,  $1/p \times pqr : 1/q \times pqr : 1/r \times pqr$  (LCM=pqr)
- ❖ **Step 5:** Reduce to lowest terms & enclose these integers in small parentheses.  
i.e. Miller indices ( $h$   $k$   $l$ ) of the crystal  $\rightarrow (qr : pr : pq) = (hkl)$

### **Example 1:**

- ❖ **To obtain Miller indices for the intercepts  $a$ ,  $b/2$ ,  $3c$  in a cubic crystal.**
- ❖ Step 1: A plane makes intercepts:  $a$ ,  $b/2$ ,  $3c$
- ❖ Step 2: Intercepts:  $1, 1/2, 3$  ( since lowest ratio's when  $a=b=c$ )
- ❖ Step 3: Reciprocals  $1/1, 2/1, 1/3$
- ❖ Step 4: Multiplying with their LCM 3
  - ❖  $1 \times 3, 2 \times 3, 1/3 \times 3 \rightarrow 3, 6, 1$
- ❖ Step 5: Miller indices of the given crystal
  - (hkl) = (361).

### **Example 2:**

- ❖ **To obtain Miller indices for the intercepts  $2$ ,  $3$ , &  $4$  in a cubic crystal.**
- ❖ Step 1: A plane makes intercepts as  $2$ ,  $3$ , &  $4$  along  $x$ ,  $y$  &  $z$  axes
- ❖ Step 2: Intercepts  $\rightarrow 2, 3, 4$  ( since lowest ratio's when  $a= b=c$  )
- ❖ Step 3: Reciprocals  $\rightarrow 1/2, 1/3, 1/4$
- ❖ Step 4: Multiplying with their LCM 12)
  - $1/2 \times 12, 1/3 \times 12, 1/4 \times 12 \rightarrow 6, 4, 3$
- ❖ Step 5: Miller indices of the chosen crystal
  - (hkl) = (643)

### **Important salient features of Miller Indices**

- ❖ Miller indices give the orientation of the crystal plane.
- ❖ A plane parallel to one of the coordinate axes has an intercept of infinity.
- ❖ If the miller indices of two planes have the same ratio [i.e., (844) & (422) or (211)], then the planes are parallel to each other.
- ❖ All parallel planes have the same miller indices.
- ❖ Plane passing through origin is defined in terms of Parallel planes having non-zero intercepts.
- ❖ If (hkl) are the miller indices then  $a/h, b/k$  &  $c/l$  are the intercepts for corresponding lattice parameters  $a, b$  &  $c$ .
- ❖ If (hkl) are the Miller indices of the plane, then the plane cuts the axes into  $h, k, l$  equal segments respectively.
